

Planning a Solid-Liquid Separation System to Meet Manure Treatment and Management Goals

2015 Midwest Manure Summit
 February 25, 2015
 Radisson Hotel & Conference Center, Green Bay, Wisconsin
 John P. Chastain, Ph.D.
 Professor and Extension Agricultural Engineer

What is Solid-Liquid Separation?

- Manure is a mixture of organic solids, plant nutrients, minerals and water.
- Solid-liquid separation is a process that divides the manure into two fractions. One that is mostly solids and the other is mostly liquid.
- So when we say a process removes total solids, nitrogen, phosphorous, or some other component from manure we simply mean that a portion of one of these components is moved to the part that is mostly solids.

Example: This flighted conveyor screen repackaged components of flushed dairy manure into solids.

	High Bedding (SC)	Moderate Bedding (MO)
TS Removed	61%	45%
TN Removed	49%	17%
Org-N Removed	52%	19%
TP Removed	51%	10%
Separated Solids Prod./day	51 lb/1000 lb LW	23 lb/1000 lb LW

Screen size = 0.059 inches

Purpose

- Provide a summary of liquid-solid separation options
- Discuss how these options fit or do not fit for manure treatment. (Dairy & Swine)
- Share some system layouts to help with planning.

Why you may *not need* solid-liquid separation on your farm. (1)

- If the animal operation is fully integrated with crop production in such a way that all plant nutrients are being used to grow grains or valuable crops. (Soil-test P not a problem.)
- Typically means you farm enough to spread manure to meet P_2O_5 or K_2O needs, proper credit for available manure N.
- Apply the needed fertilizer N at optimum rates and times.

Why you may *not need* solid-liquid separation on your farm. (2)

- Dairy manure is currently handled and stored as a slurry.
- Manure forms a reliable crust. (Odor control most of the time.)
- Plenty of land is available close by to use the plant nutrients.

Why you may *not need* solid-liquid separation on your farm. (3)

- You remove manure from barns as a slurry and use anaerobic digestion to destroy as many solids (VS) as possible to generate methane for bioenergy.
- Solid-liquid separation prior to the digester will reduce loading rate and biogas production.
- Plenty of land is available close by to use the valuable plant nutrients in treated slurry.

Why you may *not need* solid-liquid separation on your farm. (4)

- You animal operation is small and cannot realize a benefit from the cost of equipment and maintenance.
- You cannot define an economic or environmental benefit from the added expense.

Why Use Solid-Liquid Separation?

- | | |
|--|---|
| <input type="checkbox"/> Remove solids to facilitate pumping. | <input type="checkbox"/> Generate separated solids to make compost or stall bedding |
| <input type="checkbox"/> Reduce organic loading prior to biological treatment (e.g. lagoon) | <input type="checkbox"/> Move excess P from manure to solids to facilitate transport to remote fields |
| <input type="checkbox"/> Remove <i>liquid</i> from flushed manure prior to anaerobic digestion | <input type="checkbox"/> Improve uniformity of solids & plant nutrients in larger liquid part. |
| <input type="checkbox"/> Remove solids & plant nutrients <i>after</i> digestion. | <input type="checkbox"/> <i>First step in treatment</i> |

Liquid-Solid Separation Options

1. Separation based on **particle size** – *screens & presses.*
2. Separation based on **density of the manure** – *gravity settling, centrifuges & cyclones*
3. *All data are from a literature review in a publication that will be available from NRCS.*

Some screen type separators

Mechanical Separation – Screens

- Liquid manure flows through a screen.
- Particles that are captured by the screen are removed from the liquid manure stream.
- The liquids that flow through the screen go on to a storage structure, lagoon or other treatment method.
- Only pressure to drive separation comes from gravity or the flow of the manure.

Removal of solids, N, & P from **dairy manure** using a 0.030" (0.75 mm) *rotating screen*.

Influent TS	Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P Removed
0.5%	0%	3%	VL	VL
3%	14%	4%	VL	VL

Manure solids removed by rotating screen had a solids content of 6% to 11%. Too wet to handle as a solid. (Hegg et al., 1981)

Issues with using simple screen separators

- ❑ Large screen sizes needed to keep up with manure flow from barns. Flow matching is needed.
- ❑ Small screens for high capture requires low processing flow rates.
- ❑ Fine screens turn liquid manure into slurry and liquid manure. Separated solids are often too wet for optimal storage and handling as a solid. (Odor, flies)

Mechanical Separation – Presses

- ❑ Applies pressure to force more liquids through a small screen.
- ❑ Pressing can be provided by a screw, perforated belts, or filter plates.
- ❑ Can be used with smaller screens than stationary screens.
- ❑ Separated solids can be piled and handled as a solid. (Less odor and flies)

Screw & Belt Press Separators

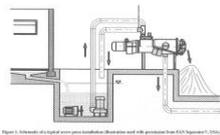

Figure 1. Schematic of a typical screw press separator. (Reprinted with permission from ERS, September 12, 2004)

Screw Press Separator: Dairy Manure

Screen Size	TS of Manure	TS Removed	N Removed	P Removed
0.020"	2.6%	25%	8%	6%
0.029"	10%	71%	24%	24%
0.094"	2%	16%	?	9%
0.094"	4.9%	33%	13%	10%
0.094"	10%	47%	?	29%

Separated solids had TS of 25% to 29% and stacked well.

Presses have also been used to remove solids from anaerobically treated manure – lagoon sludge and digester solids.

Screw Press Separator: **Anaerobically Digested Dairy Manure**

Screen Size	TS of Manure	TS Removed	N Removed	P Removed
0.020"	7.5%	50%	16%	24%
0.029"	8.3%	47%	17%	20%
0.089"	5.5%	4%	1%	1%

(Gooch et al., 2005).

Separated solids had TS of 24% to 29% and stacked well.

Belt Press: **Dairy & Swine Manure**

Screen Size	TS of Manure	TS Removed	N Removed	P Removed
Dairy				
0.039"–0.079"	7%	32%	10%	15%
Swine				
0.0039"	3.0%	47%	32%	18%
0.0039"	8.0%	59%	35%	21%
0.039"–0.079"	5.7%	22%	10%	20%

Separated solids had TS of 14% to 19% and were too wet to stack well.

Issues with using press separators

- ❑ High pressure provides dry solids, but forces some large particles through screen.
- ❑ Trade-off between particle capture and dryness of pressed cake.
- ❑ Low process flow rate.
- ❑ Tight tolerances can lead to screen replacement & higher maintenance costs.

Trade offs to consider when using mechanical separators

- *Presses* can remove more total and volatile solids, N and P than screens, but work best with slurry manure and small screen openings.
- *Presses* can yield drier solids than screens.
- *Presses* are slower than screens.
- *Screens* with small openings can remove a significant amount of solids & plant nutrients but yield wet separated solids (slurry) at high process flow rates.
- *Screens* with large openings can handle high flow rates but only remove large solids. Solids pile easily.

Combination of an in-channel flighted conveyor screen with a small screw press helped to provide additional dewatering. But **separated swine solids** were still too wet to stack well.

Liquid-solid separator that employs three techniques: fine stationary incline screen (0.020 in), screw press, and an inclined flighted conveyor screen (courtesy of US FARM Systems, Tulare, CA).

Removal of solids, N, & P from dairy manure using a combination machine (US FARM Systems).

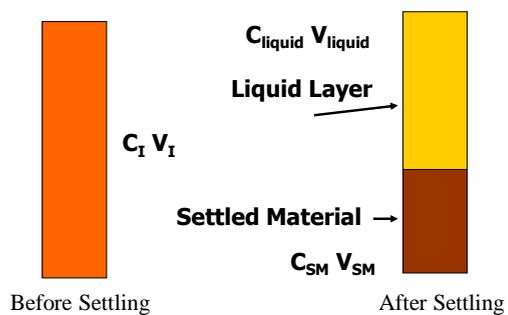

Influent TS	Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P Removed
< 1.5%	50%	56%	23%	20%

Flushed manure, stalls bedded with dried dairy solids, separated solids TS = 23% (Chastain, 2009).

Liquid-Solid Separation by Settling

During gravity settling liquid manure separates into liquid and settled material layers.

Factors that determine the effectiveness settling

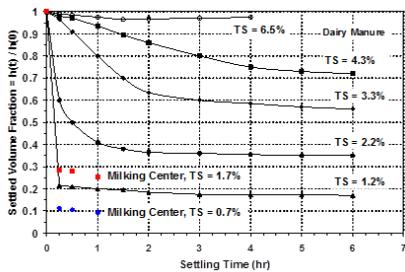

1. Particles must be heavier than water.
2. There must be enough water in the mixture for the solids to settled and form a large liquid layer.
3. Want to provide sufficient settling conditions.
 - very low flow velocity
 - Long enough detentions time for solids to be captured.

Gravity settling can be used for...

- Removing solids & nutrients from runoff from outdoor lots.
- Flushed manure from freestall buildings, and milking centers, and flushed swine facilities.

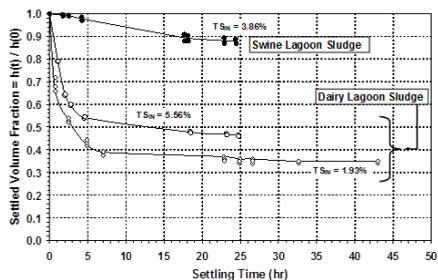

Gravity settling cannot be used to treat dairy manure with a TS greater than 3%.

Gravity settling cannot be used to treat slurry manure.

Gravity settling also does not work well for thick lagoon water and sludge mixtures.

Removal of solids, N, and P from liquid dairy manure by gravity settling. (Inflow TS = 1.7%)

Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P ₂ O ₅ Removed	K ₂ O Removed
61%	66%	41%	45%	25%

Gravity settling can greatly reduce the loading of solids and phosphorus on a storage or lagoon. Volume of settled solids was 25% of flush volume (SVF = 0.25)

Solids and Nutrient Content of Liquid Dairy Manure Before & After Settling for 1 hour.

	Flushed Manure	Liquid From Settling	Settled Solids
TS	1.7%	0.9%	4.1%
Pounds / 1000 gallons			
VS	111.6	50.5	290.7
Org-N	3.8	1.4	10.7
TAN	6.3	6.5	6.4
P ₂ O ₅	3.4	2.5	6.0
K ₂ O	7.6	8.0	7.8

Dairy: Change in ratio of PAN and P₂O₅

	Flushed Manure	Liquid From Settling	Settled Solids
	Pounds / 1000 gallons		
Org-N	3.8	1.4	10.7
TAN	6.3	6.5	6.4
PAN- incorp	7.3	6.0	11.5
P ₂ O ₅	3.4	2.5	6.0
PAN:P ₂ O ₅	2.1	2.4	1.9

Most grain crops want PAN:P₂O₅ = 2.2 to 2.5.

	Flushed Manure	Liquid From Settling	Settled Solids
PAN:P ₂ O ₅	2.1	2.4	1.9

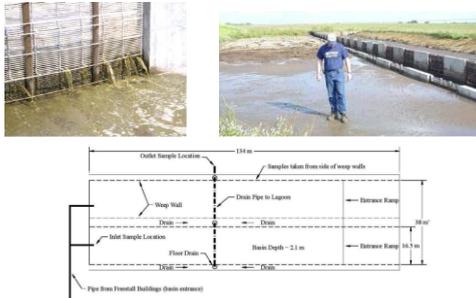

Gravity settling of **dairy manure** improves the balance of N to P₂O₅ for many crops for the liquid part while increasing the relative P₂O₅ content in the separated solids.

Removal of solids, N, and P from flushed **swine manure** by **gravity settling**. (Inflow TS = 1.0%)

Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P ₂ O ₅ Removed	K ₂ O Removed
53%	58%	33%	68%	17%

Gravity settling can greatly reduce the loading of solids and phosphorus on a storage or lagoon.

Weeping-wall, drain dry settling basins combine treatment & storage. How big do you want?

Weeping Wall Settling Basin: Dairy Manure

	TS of Manure	TS Removed	N Removed	P Removed
Meyer et al. (2004)				
	1.1 – 1.8%	49-63%	?	?
Mukhtar et al. (2011)				
Two-stage	3.0%	88%	84%	86%

Separated solids had TS of 30% to 36%.
 Must be sized based on number of cows & storage period.
 1.67 ft³/cow/day – manure solids
 2.22 ft³/cow/day – manure solids + sand bedding (Fulhage, 2003)

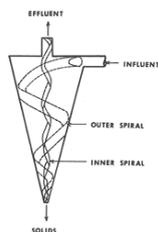

Main issues with gravity settling to take into account are...

- Cost and permitting of settling basin or pond (large foot print)
- Potential for increase in odor if too wet.
- Cost of permeable cover that can greatly reduce odor. (Settling ponds)
- Purchase and maintenance cost of agitation and pumping equipment.
- Requires transport to fields with different equipment than the liquid part.

Liquid-Solid Separation by Centrifuge & Hydrocyclones (Works for Dairy & Swine)

Decanter Centrifuge

Hydrocyclone

Removal of solids, N, and P from liquid swine manure using a *centrifuge*. (Inflow TS = 1.5%)

Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P ₂ O ₅ Removed	K ₂ O Removed
38%	44%	21%	61%	14%

A centrifuge provides removal similar to settling in much less space and yields a pile of solids (Westerman and Ogejo, 2005).

Removal of solids, N, and P from swine lagoon sludge mixture using a *centrifuge*. (Inflow TS = 1.6%)

Total Solids Removed	Volatile Solids Removed	Nitrogen Removed	P ₂ O ₅ Removed	K ₂ O Removed
32%	25%	26%	63%	11%

A centrifuge can be used to process dilute swine lagoon sludge mixtures (Westerman and Ogejo, 2005).

Addition of Polymers (PAM) and Metal Salts – works for dairy & swine manure

- ❑ These chemicals can be used to improve the performance of any method of liquid-solid separation.
- ❑ Solids and P removals of 70% to 90% can be obtained.
- ❑ Requires TS less than 6%
- ❑ PAM, Alum, Iron Chloride, and others can be used alone or in combination *at proper dose*.

Effect of adding alum or iron chloride to dilute *swine manure* prior to settling (TS in = 0.24%).

	Coagulant Concentration					
	40 mg/L		250 mg/L		625 mg/L	
	TSR (%)	PR (%)	TSR (%)	PR (%)	TSR (%)	PR (%)
Control	52.6	19.0	50.1	17.8	50.2	14.6
Alum	53.6	21.0	86.5	73.9	92.8	90.9
Iron Chloride	62.2	30.0	90.9	82.7	91.9	78.2

TSR = Total Solids Removal and PR = Phosphorous Removal (adapted from Powers and Flatow, 2002).

Treatment of liquid *swine manure* (TS = 1.5%) using a settling pond with and without addition of alum (UGA, Worley & Das, 2000)

	Settling Pond – No Alum	Settling Pond – 2900 mg Alum/L
TS - Removed	60%	70%
P - Removed	38%	75%
N - Removed	20%	20%
K- Removed	8%	8%

Disadvantage of alum or iron salts is that it makes the soluble P unavailable to plants.

Treatment of pit-recharge **swine** manure by addition of **PAM** followed by screening (0.039) (Vanotti et al., 2002)

	No PAM	60 mg PAM/L	120 mg PAM/L
TS - Removed	9%	39%	54%
TSS - Removed	15%	68%	93%
VSS - Removed	17%	69%	93%
P - Removed	10%	53%	74%
N - Removed	7%	23%	33%

Treatment of dilute **swine lagoon sludge** mixture using a centrifuge with and without chemicals (Westerman and Ogejo, 2005)

	No Chemicals	C + F	C+F+L
TS - Removed	32%	51%	76%
TSS - Removed	41%	73%	88%
VS - Removed	25%	55%	79%
P - Removed	63%	54%	82%
N - Removed	26%	40%	48%

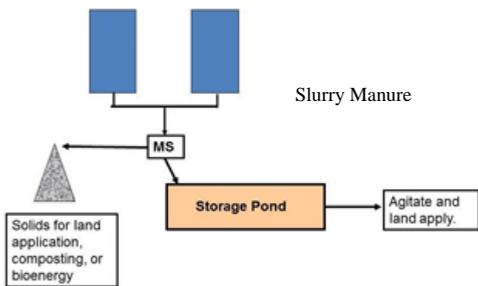

C = coagulant, F = flocculent, L = lime

Chemicals can be used to remove 70% to 90% of the solids and P for most methods of liquid-solid separation

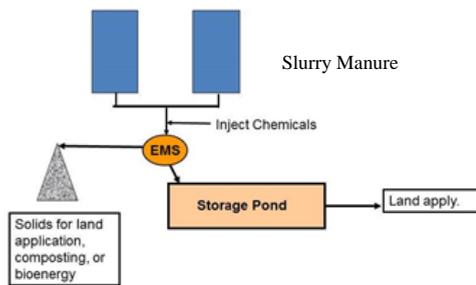

- Need proper dose
- Need proper mixing
- Need proper dilution
- Need \$\$\$

Some systems layouts to consider...

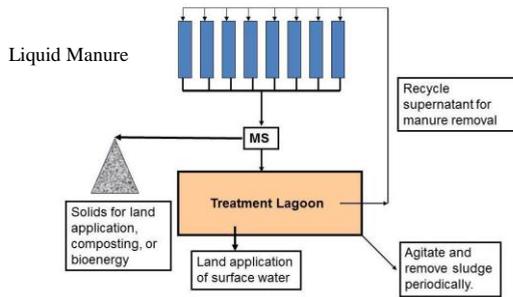

Using mechanical separation (MS) to reduce solids in storage to improve pumping and to provide solids for bedding or remote land application.

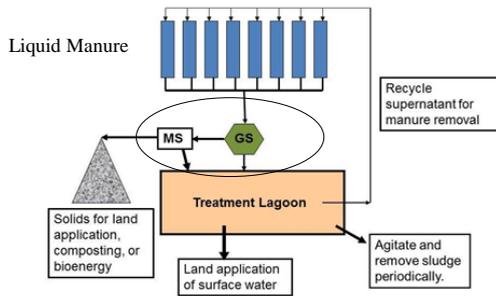

Chemically enhanced mechanical separation (EMS) to remove large amounts of solids & P.

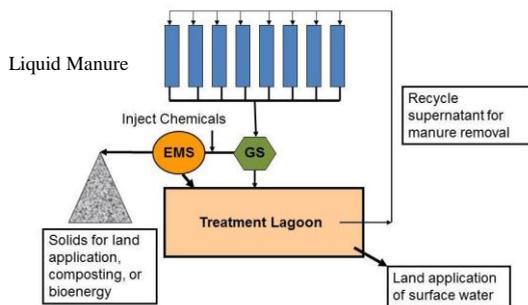

Use of a mechanical separator (MS) to reduce loading on a lagoon or storage. [Flow rate?](#)

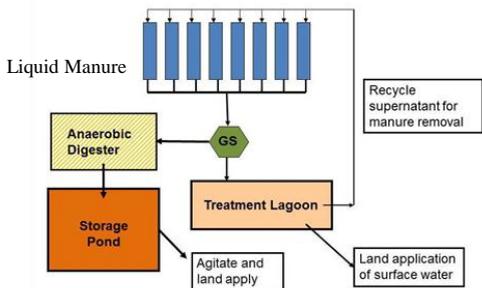

Gravity settling (GS) prior to mechanical separation (MS) can allow small screens to be used with high manure flow rates associated with flush systems.

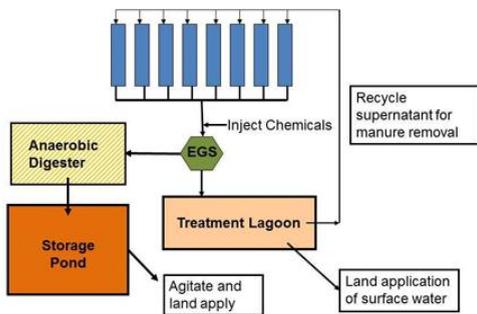

Gravity settling can be used to make high-rate mechanical separation easier – also reduces chemical costs.

Use of gravity settling (GS) to concentrate volatile solids prior to loading an anaerobic digester.

Chemically enhanced gravity settling (EGS) to concentrate 80% or more of the volatile solids prior to loading an anaerobic digester.

Settling to thicken liquid manure before digestion and enhanced mechanical separation after.
